

# Selected USGS Data Collection and Analysis Products, Difficult Run Watershed, Fairfax Co, Virginia, 1979 - 2018

Materials prepared for presentation at the 2023 Metropolitan Washington Council of Governments Water Summit Series: COG's Freshwater Salinization Monitoring Program Update Webinar

February 15, 2023

Jeffrey Chanat (jchanat@usgs.gov)  
James Webber, Aaron Porter, and John Jastram

Streams from U.S. Geological Survey National Hydrography Geodatabase (2013)  
Land use from Homer and others (2015)  
Drainage area from Hayes and Wiegand (2006)  
Roads are from U.S. Census Bureau TIGER/Line shapefiles (2015)  
North American Datum of 1983

# USGS data collection and analysis in the Difficult Run watershed is leading to insights on salinization

- Difficult Run is the largest Fairfax County watershed (58 mi<sup>2</sup>) and contains a mixture of urban land (residential, commercial, and industrial area).
- Sampling strategies
  - **USGS gage at Great Falls:** A stream-gage has been operated at the outlet of the watershed since 1935. Water-quality has been collected since 1985. Difficult Run is one of 123 monitored watersheds in the Chesapeake Bay Non-tidal Monitoring Network.
  - **Synoptic:** USGS has collected dry-weather discharge and water-quality samples throughout the watershed annually since the early 2010's.

35 Synoptic sampling locations (discharge, SC, nutrients, major ions)

Difficult Run nr Great Falls, VA

Difficult Run (area=57.82 mi <sup>2</sup> )	

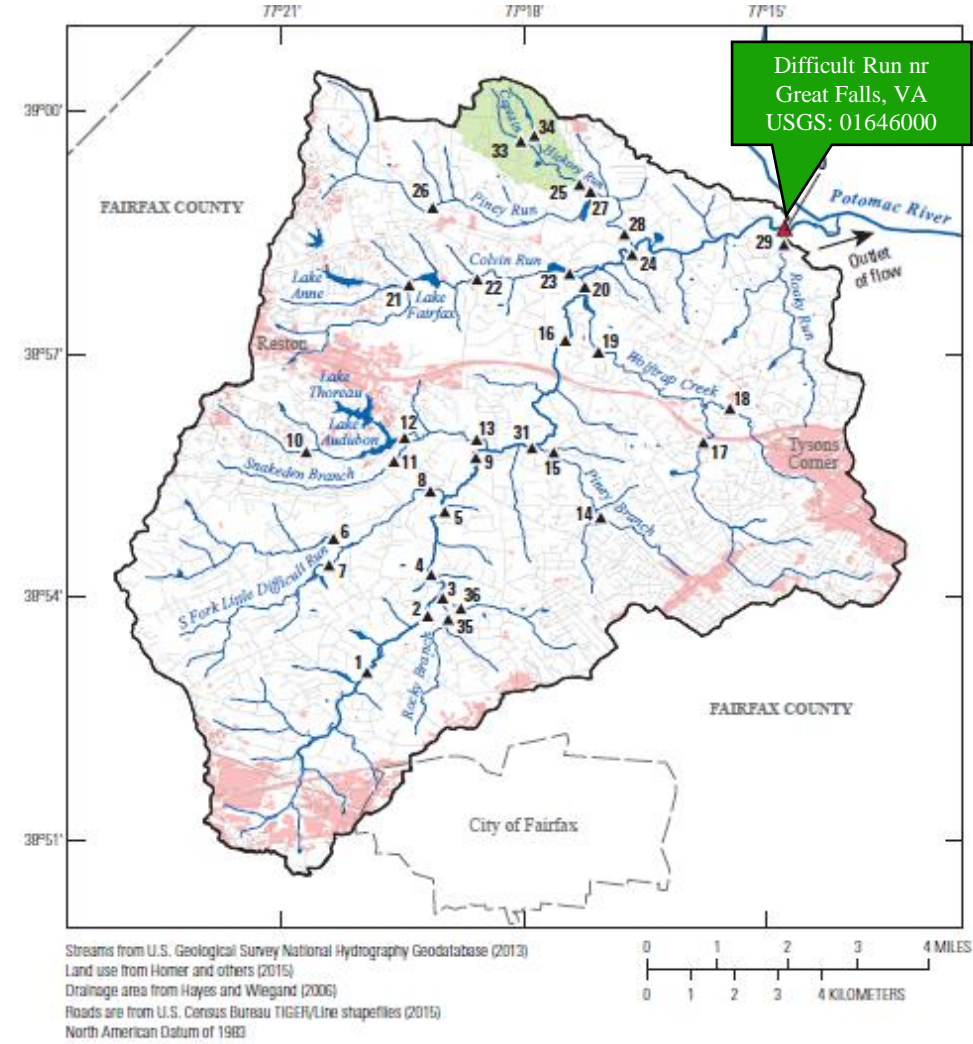

## What are we learning?

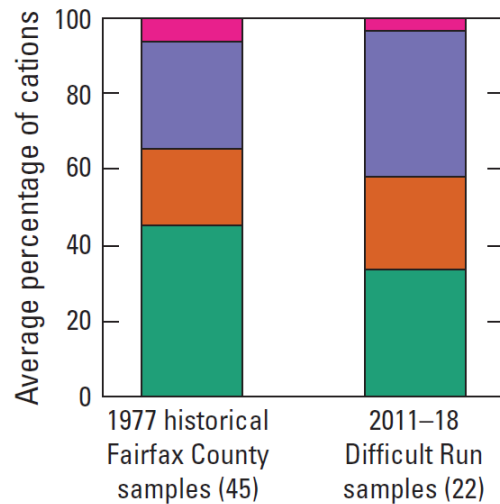

# Specific conductance increased at the Difficult Run streamgauge

Average annual specific conductance values tripled at the Difficult Run stream-gauge since the early 1980s, from about 100 uS/cm to more than 300 uS/cm.

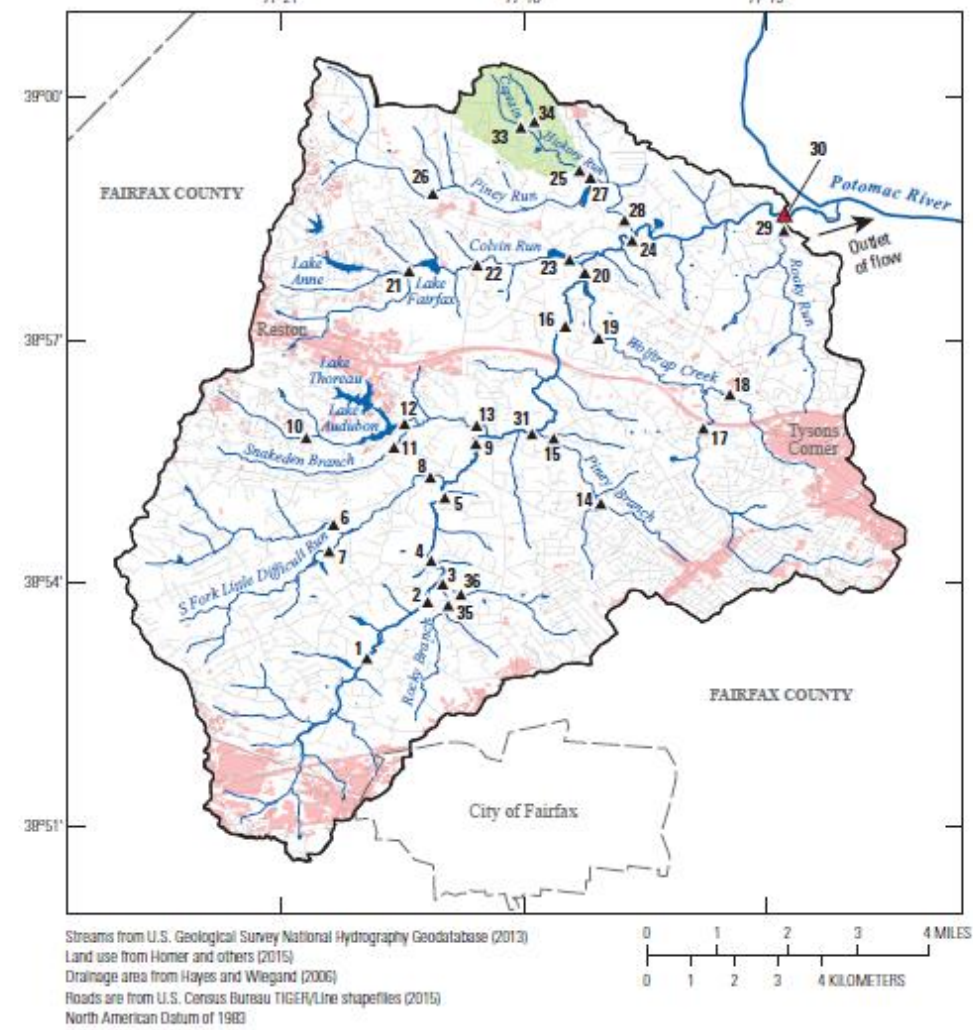

# Increases in specific conductance result from increases in Na<sup>+</sup> and Cl<sup>-</sup>

- EXPLANATION**
- Calcium
  - Magnesium
  - Sodium
  - Potassium

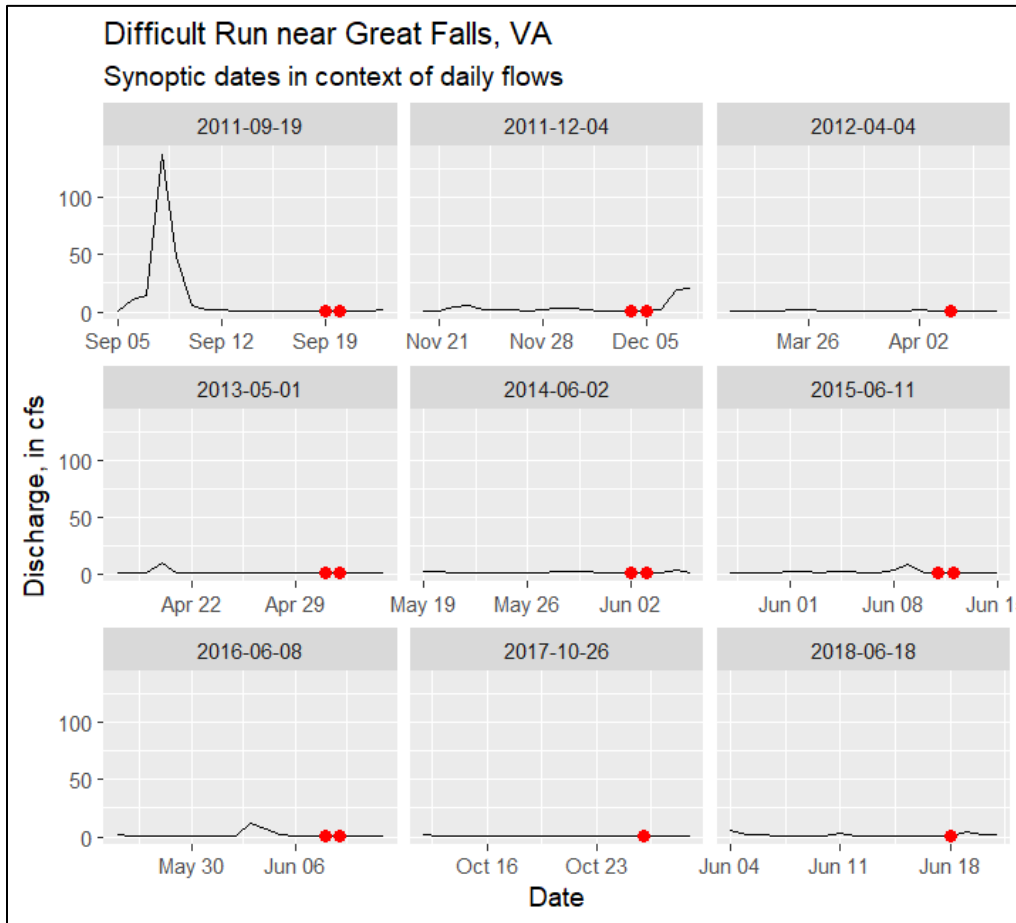

- EXPLANATION**
- Bicarbonate
  - Chloride
  - Sulfate
  - Nitrate

On average, calcium and bicarbonate were the most prevalent ions in the 1977 Fairfax County samples, whereas sodium and chloride were the most prevalent ions in the 2011-2018 Difficult Run samples.

  - Major ions
  - $\delta^{18}\text{O}$ ,  $\delta^{15}\text{N}$

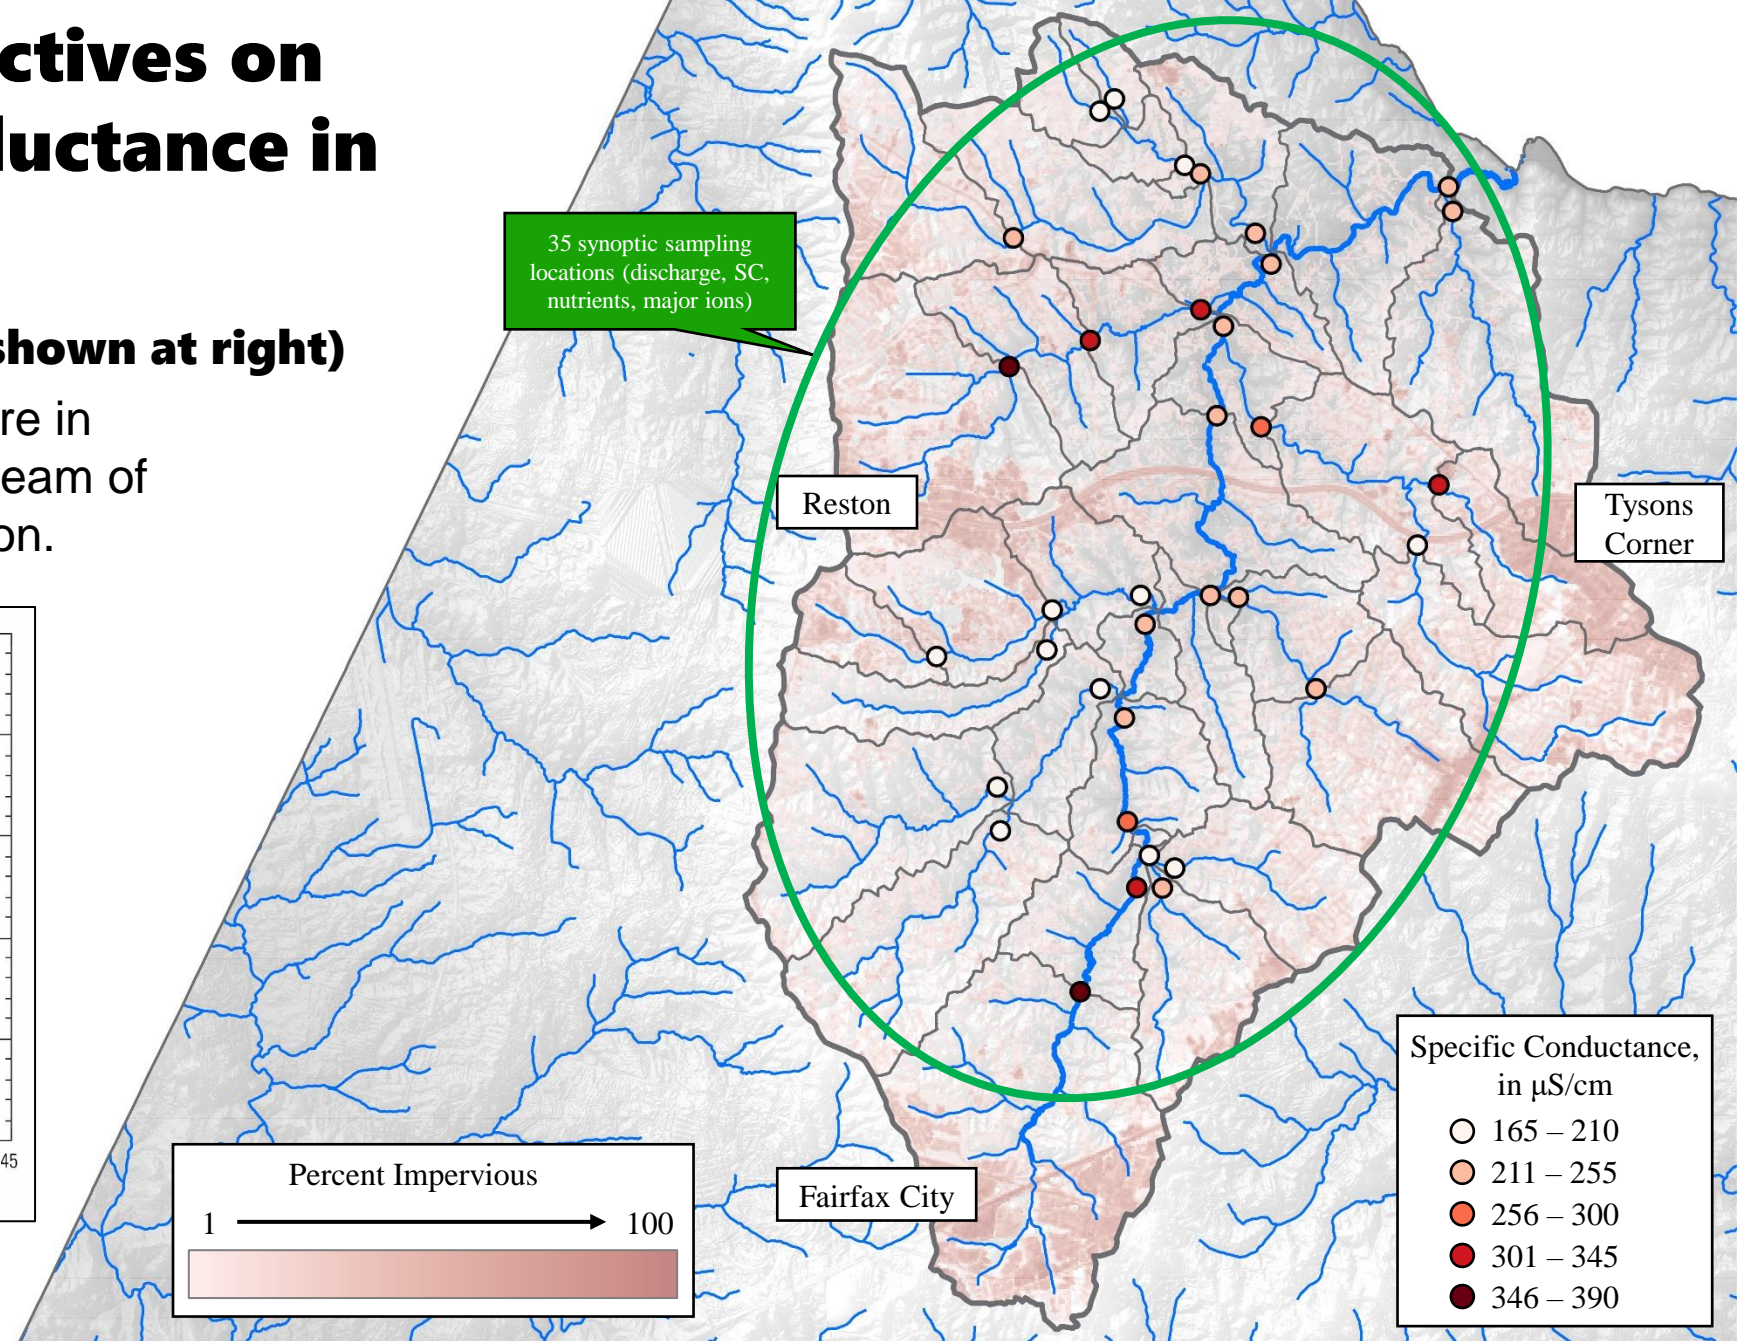

# Two analytical perspectives on synoptic specific conductance in Difficult Run streams

## 1. Map sampled concentrations (shown at right)

High values of specific conductance are in watershed areas immediately downstream of Fairfax City, Tysons Corner, and Reston.

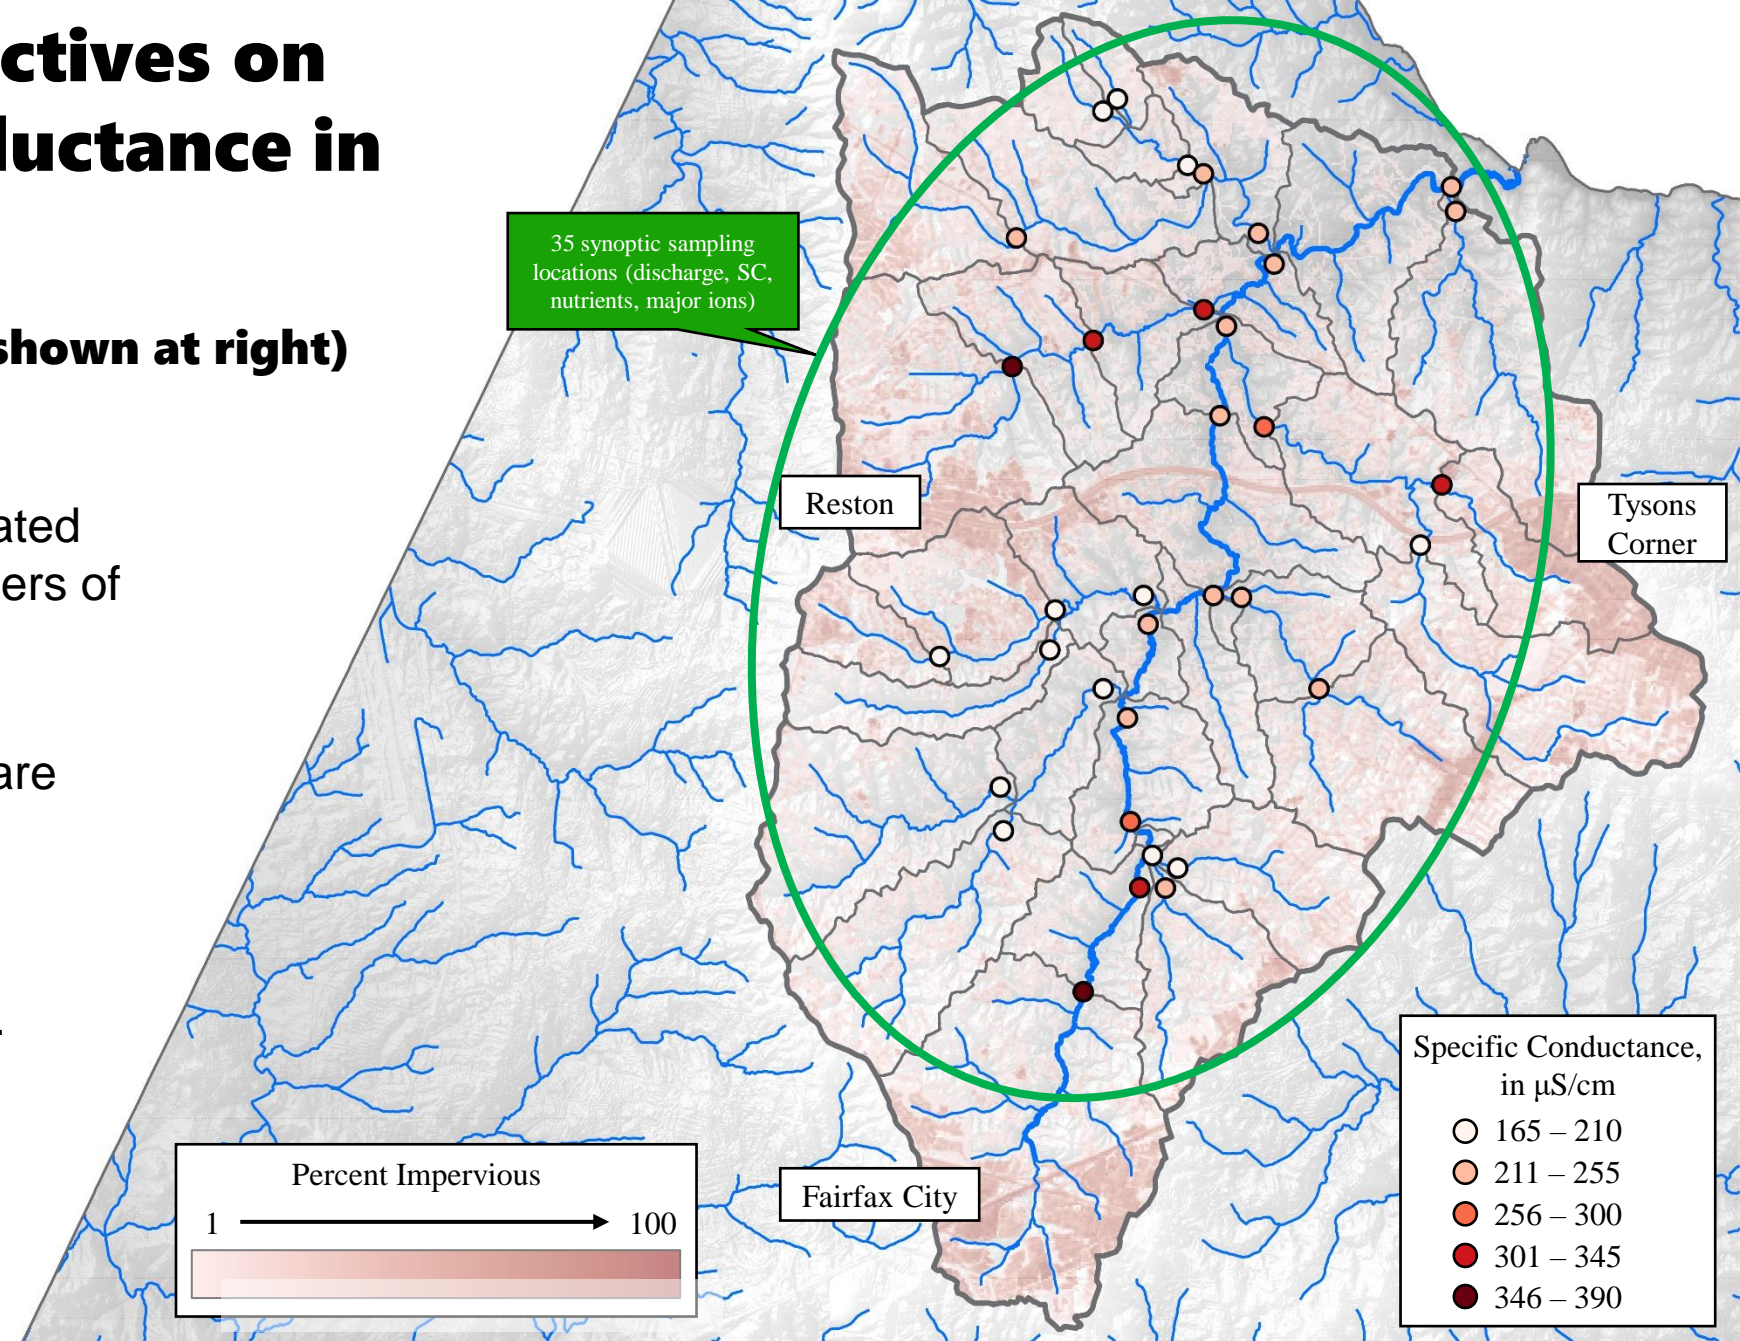

# Two analytical perspectives on synoptic specific conductance in Difficult Run streams

## 1. Map sampled concentrations (shown at right)

Limitations:

- Upstream contributing area associated with each sample varies over 2 orders of magnitude.
- In-stream observations violate regression assumptions (samples are not independent).
- More difficult to explicitly locate problematic impervious areas as sampled watershed size increases.

# Two analytical perspectives on synoptic specific conductance in Difficult Run streams

2. Alternately, **consider the incremental sub-watersheds which contribute to each synoptic sampling location** (small area between nearest upstream and downstream sampling location).

- Close coupled H<sub>2</sub>O/conservative solute mass balance over entire sampling domain.
- Knowing the incremental discharge between sampling points, pose question as:

*For each incremental watersheds' contribution to streamflow volume, what must the local concentration have been to lead to the observed in-stream concentration, considering the role of upstream inputs?*

- This approach improves our ability to pinpoint problematic source areas.

$$Q_{inc} = Q_{dns} - Q_{ups}$$

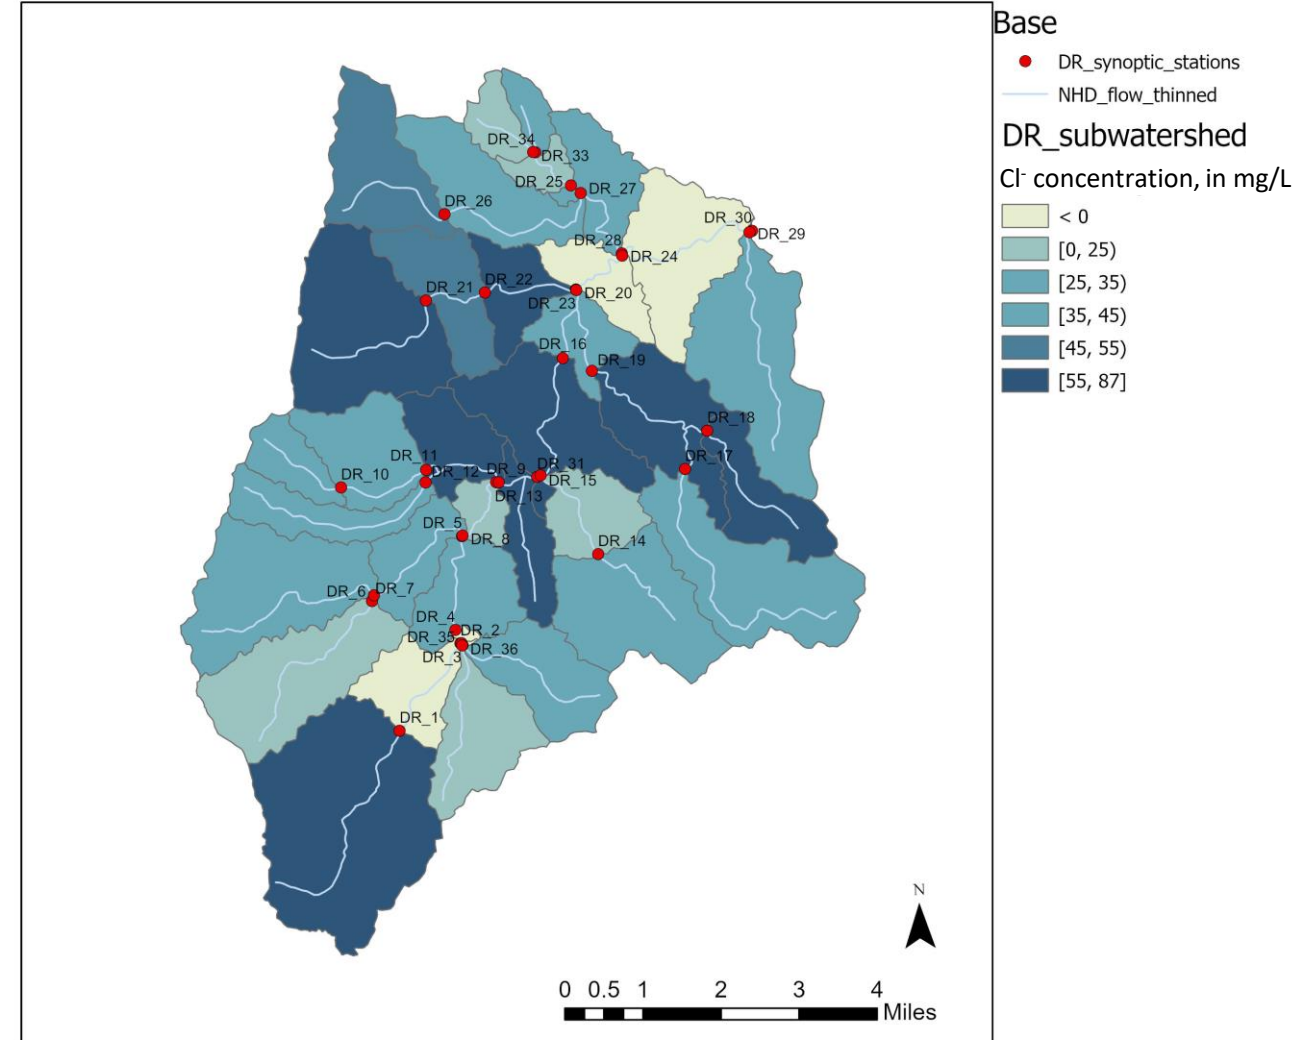

$$C_{inc} \cdot Q_{inc} = C_{dns} \cdot Q_{dns} - C_{ups} \cdot Q_{ups}$$

# Two analytical perspectives on synoptic specific conductance in Difficult Run streams

2. Alternately, **consider the incremental sub-watersheds which contribute to each synoptic sampling location** (small area between nearest upstream and downstream sampling location).

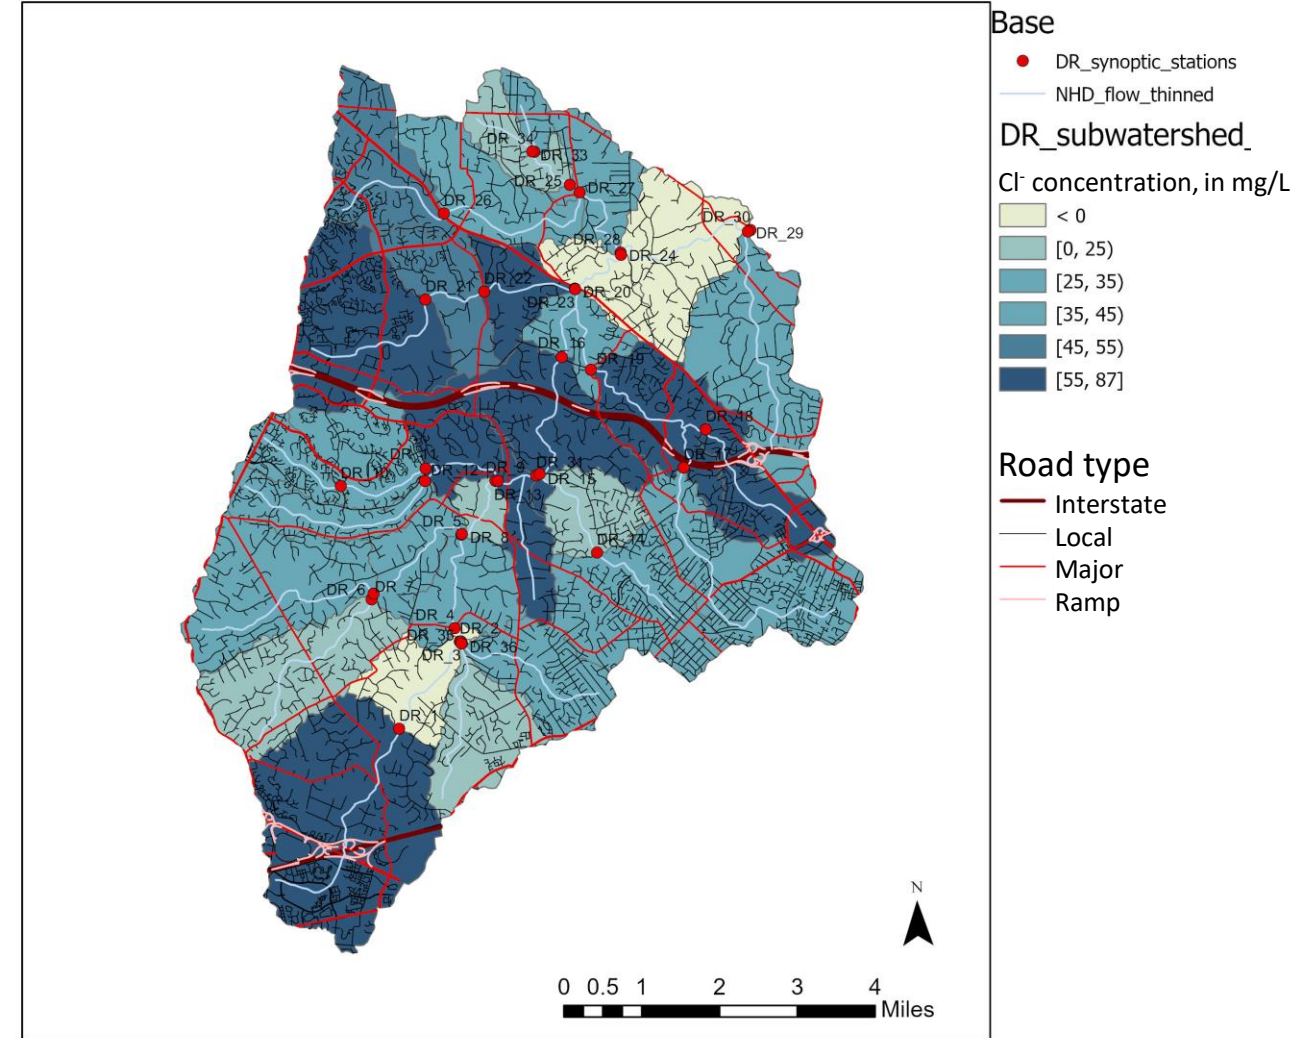

- A map of **estimated chloride concentration of incremental channel inflow, April 4, 2012**
- Pattern revealed suggests the significance of connected areas

# Two analytical perspectives on synoptic specific conductance in Difficult Run streams

2. Alternately, **consider the incremental sub-watersheds which contribute to each synoptic sampling location** (small area between nearest upstream and downstream sampling location).

- A map of **estimated chloride concentration of incremental channel inflow, April 4, 2012**
- Pattern revealed suggests the significance of connected areas
- Overlay associates pattern with **interstate roads and/or co-located impervious area**

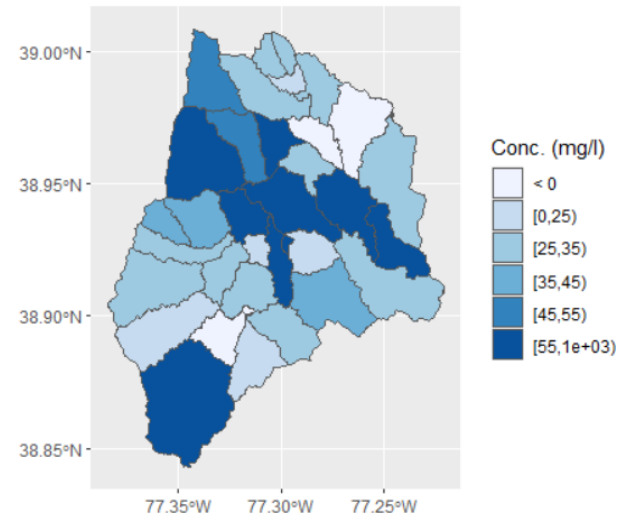

# Two analytical perspectives on synoptic specific conductance in Difficult Run streams

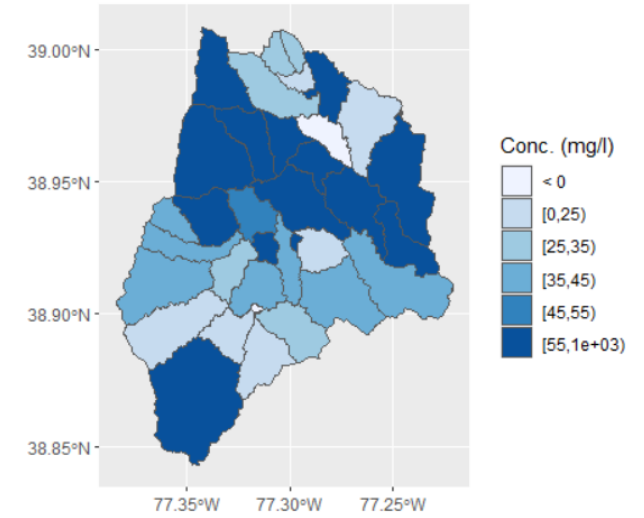

2. Alternately, **consider the incremental sub-watersheds which contribute to each synoptic sampling location** (small area between nearest upstream and downstream sampling location).

- Pattern revealed suggests the significance of connected areas
- This appears to be a **stable dry-weather pattern in Difficult Run**
- Next steps:
  - Explain these patterns by including spatially explicit predictors such as lithology, % impervious, length of all roads, length of major roads, etc.
